

# *COSC252: Programming Languages Lecture: Bottom Up Parsing*

Jeremy Bolton, PhD  
Asst Professor

For the excellent slides: A very special thanks to the faculty at Stanford, and the authors of THE Dragon Book, Aho et al.

# *Outline*

## I. Bottom Up Parsing

# *Different Types of Parsing*

- **Top-Down Parsing**
  - Beginning with the start symbol, try to guess the productions to apply to end up at the user's program.
- **Bottom-Up Parsing**
  - Beginning with the user's program, try to apply productions in reverse to convert the program back into the start symbol.

# *What is Bottom-Up Parsing?*

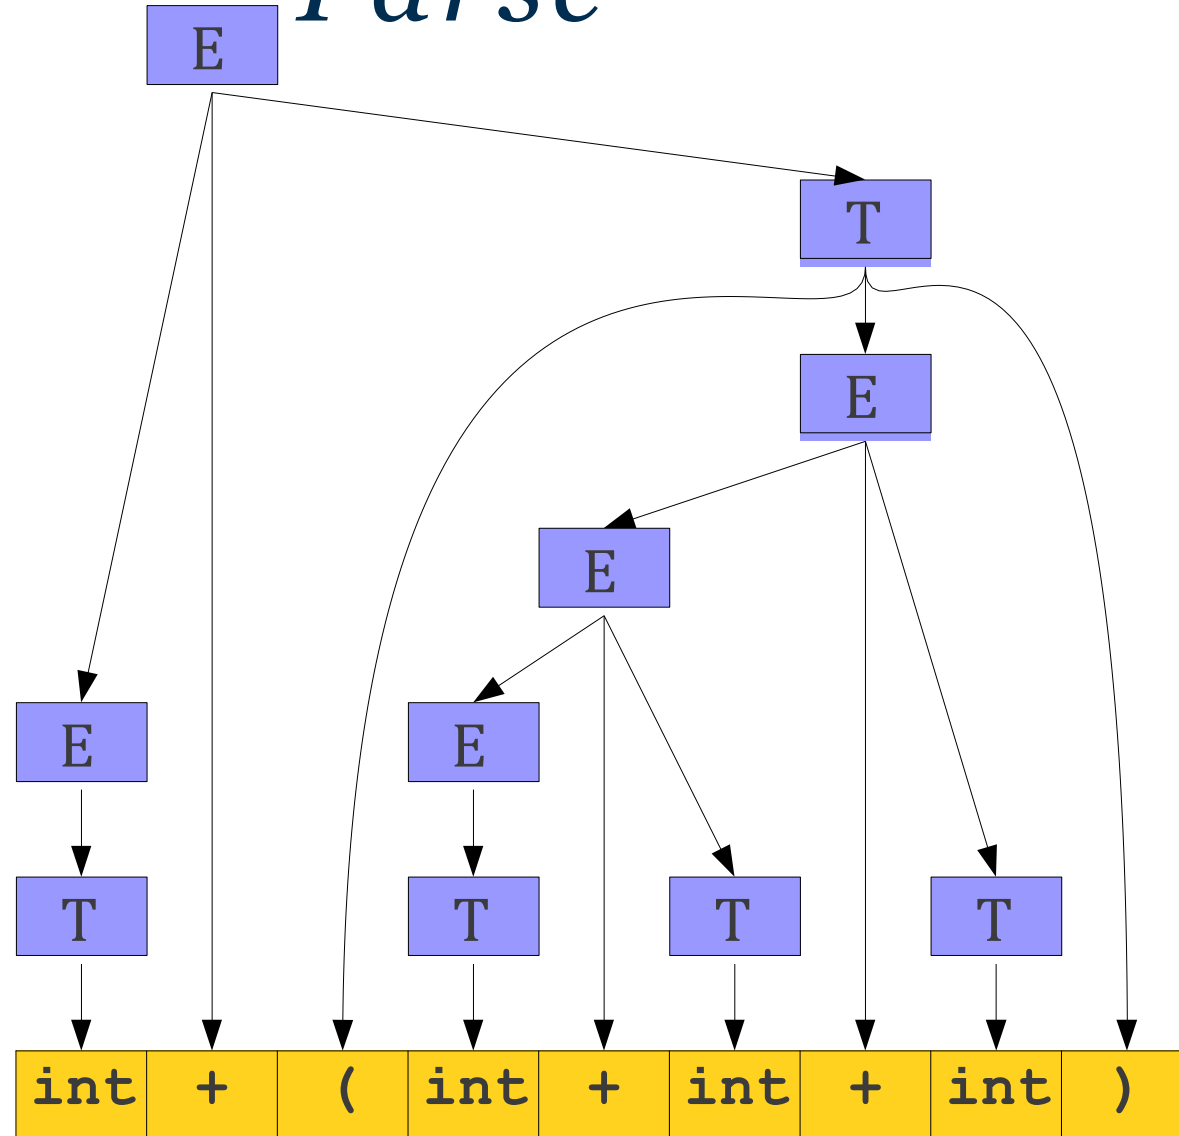

- Idea: Apply productions **in reverse** to convert the user's program to the start symbol.
- As with top-down, could be done with a DFS or BFS, though this is rarely done in practice.
- We'll be exploring 4-ish **directional, predictive**
- bottom-up parsing techniques:

**Directional:** Scan the input from left-to-right.

**Predictive:** Guess which production should be inverted.

# One View of a Bottom-Up Parse

**E** → **T**  
**E** → **E** + **T**  
**T** → *int*  
**T** → (**E**)

# A Second View of a Bottom-Up Parse

<b>E</b> → <b>T</b>		int + (int + int + int)
<b>E</b> → <b>E</b> + <b>T</b>	⇒	<b>T</b> + (int + int + int)
<b>T</b> → int	⇒	<b>E</b> + (int + int + int)
<b>T</b> → ( <b>E</b> )	⇒	<b>E</b> + ( <b>T</b> + int + int)
	⇒	<b>E</b> + ( <b>E</b> + int + int)
	⇒	<b>E</b> + ( <b>E</b> + <b>T</b> + int)
	⇒	<b>E</b> + ( <b>E</b> + int)
	⇒	<b>E</b> + ( <b>E</b> + <b>T</b> )
	⇒	<b>E</b> + ( <b>E</b> )
	⇒	<b>E</b> + <b>T</b>
	⇒	<b>E</b>

# A Second View of a Bottom-Up Parse

<b>E</b> → <b>T</b>		int + (int + int + int)
<b>E</b> → <b>E</b> + <b>T</b>	⇒ <b>T</b> +	(int + int + int)
<b>T</b> → int	⇒ <b>E</b> +	(int + int + int)
<b>T</b> → ( <b>E</b> )	⇒ <b>E</b> +	( <b>T</b> + int + int)
	⇒ <b>E</b> +	( <b>E</b> + int + int)
	⇒ <b>E</b> +	( <b>E</b> + <b>T</b> + int)
	⇒ <b>E</b> +	( <b>E</b> + int)
	⇒ <b>E</b> +	( <b>E</b> + <b>T</b> )
	⇒ <b>E</b> +	( <b>E</b> )
	⇒ <b>E</b> +	<b>T</b>
	⇒ <b>E</b>	

*A left-to-right, bottom-up  
parse is a rightmost  
derivation traced in reverse.*

# *A Third View of a Bottom-Up Parse*

int + (int + int + int)  
⇒ **T** + (int + int + int)  
⇒ **E** + (int + int + int)  
⇒ **E** + (**T** + int + int)  
⇒ **E** + (**E** + int + int)  
⇒ **E** + (**E** + **T** + int)  
⇒ **E** + (**E** + int)  
⇒ **E** + (**E** + **T**)  
⇒ **E** + (**E**)  
⇒ **E** + **T**  
⇒ **E**

Each step in this bottom-up parse is called a **reduction**.

We **reduce** a substring of the sentential form back to a nonterminal.

# A Third View of a Bottom-Up Parse

```

int + (int + int + int)
⇒ T + (int + int + int)
⇒ E + (int + int + int)
⇒ E + (T + int + int)
⇒ E + (E + int + int)
⇒ E + (E + T + int)
⇒ E + (E + int)
⇒ E + (E + T)
⇒ E + (E)
⇒ E + T
⇒ E

```

# A Third View of a Bottom-Up Parse

# *Handles*

- The **handle** of a parse tree  $T$  is the leftmost complete cluster of leaf nodes.
  - Refers to LHS non-terminal chosen during resolve step
- A left-to-right, bottom-up parse works by iteratively searching for a handle, then reducing the handle.

# *Summarizing Our Intuition*

- Our first intuition (reconstructing the parse tree bottom-up) motivates how the parsing should work.
- Our second intuition (rightmost derivation in reverse) describes the order in which we should build the parse tree.
- Our third intuition (handle pruning) is the basis for the bottom-up parsing algorithms we will explore.

This reduction  
wasn't a handle!

*The leftmost reduction isn't always the handle.*

# *Finding Handles*

- Where do we look for handles?
  - Where in the string might the handle be?
- How do we search for possible handles?
  - Once we know where to search, how do we identify candidate handles?
- How do we recognize handles?
  - Once we've found a candidate handle, how do we check that it really is the handle?

# Question One:

Where are handles?

# Where are Handles?

- Recall: A left-to-right, bottom-up parse traces a rightmost derivation in reverse.
- Each time we do a reduction, we are reversing a production applied to the *rightmost* nonterminal symbol.
- Suppose that our current sentential form is  $a\gamma\omega$ , where  $\gamma$  is the handle and  $A \rightarrow \gamma$  is a production rule.
- After reducing  $\gamma$  back to  $A$ , we have the string  $aA\omega$ .
- Thus  $\omega$  must consist purely of terminals, since otherwise the reduction we just did was not for the rightmost terminal.

# *Why This Matters*

- Suppose we want to parse the string  $\gamma$ .
- We will break  $\gamma$  into two parts,  $a$  and  $\omega$ , where
  - $a$  consists of both terminals and nonterminals, and
  - $\omega$  consists purely of terminals.
- Our search for handles will concentrate purely in  $a$ .
- As necessary, we will start moving terminals from  $\omega$  over into  $a$ .

# *Shift/Reduce Parsing*

- The bottom-up parsers we will consider are called **shift/reduce** parsers.
  - Contrast with the LL(1) **predict/match** parser.
- Idea: Split the input into two parts:
  - Left substring is our work area; all handles must be here.
  - Right substring is input we have not yet processed; consists purely of terminals.
- At each point, decide whether to:
  - Move a terminal across the split (**shift**)
  - Reduce a handle (**reduce**)

E

# *An Important Observation*

- All of the reductions we applied were to the far right end of the left area.
- This is not a coincidence; all reductions are always applied all the way to the end of the left area.
- Inductive proof sketch:
  - After no reduces, the first reduction can be done at the right end of the left area.
  - After at least one reduce, the very right of the left area is a nonterminal. This nonterminal must be part of the next reduction, since we're tracing a rightmost derivation backwards.

# *An Important Corollary*

- Since reductions are always at the right side of the left area, we never need to shift from the left to the right.
- No need to “uncover” something to do a reduction.
- Consequently, shift/reduce parsing means

**Shift:** Move a terminal from the right to the left area.

**Reduce:** Replace some number of symbols at the right side of the left area.

# *Simplifying our Terminology*

- All activity in a shift/reduce parser is at the far right end of the left area.
- Idea: Represent the left area as a stack.
- Shift: Push the next terminal onto the stack.
- Reduce: Pop some number of symbols from the stack, then push the appropriate nonterminal.

# *Finding Handles*

- Where do we look for handles?
  - **At the top of the stack.**
- How do we search for handles?
  - What algorithm do we use to try to discover a handle?
- How do we recognize handles?
  - Once we've found a possible handle, how do we confirm that it's correct?

# Question Two:

How do we search for handles?

# *Searching for Handles*

- When using a shift/reduce parser, we must decide whether to shift or reduce at each point.
- We only want to reduce when we know we have a handle.
- **Question:** How can we tell that we might be looking at a handle?

# *Exploring the Left Side*

- The handle will always appear at the end of string in the left side of the parser.
- Can *any* string appear on the left side of the parser, or are there restrictions on what sorts of strings can appear there?
- If we can find a pattern to the strings that can appear on the left side, we might be able to exploit it to detect handles.

# *Generating Left-Hand Sides*

- At any instant in time, the contents of the left side of the parser can be described using the following process:
  - Trace out, from the start symbol, the series of productions that have not yet been completed and where we are in each production.
  - For each production, in order, output all of the symbols up to the point where we change from one production to the next.

# *Recognizing Left-Hand Sides*

- Given that we have a procedure for *generating* left-hand sides, can we build a procedure for *recognizing* those left-hand sides?
- Idea: At each point, track
  - Which production we are in, and
  - Where we are in that production.
- At each point, we can do one of two things:
  - Match the next symbol of the candidate left-hand side with the next symbol in the current production, or
  - If the next symbol of the candidate left-hand side is a nonterminal, nondeterministically guess which production to try next.

# *An Important Result*

- There are only finitely many productions, and within those productions only finitely many positions.
- At any point in time, we only need to track where we are in one production.
- There are only finitely many options we can take at any one point.
- **We can use a finite automaton as our recognizer.**

# An Automaton for Left Areas

# *Constructing the Automaton*

- Create a state for each nonterminal.
- For each production  $A \rightarrow \gamma$ :
  - Construct states  $A \rightarrow a \cdot \omega$  for each possible way of splitting  $\gamma$  into two substrings  $a$  and  $\omega$ .
  - Add transitions on  $x$  between  $A \rightarrow a \cdot x\omega$  and  $A \rightarrow ax \cdot \omega$ .
- For each state  $A \rightarrow a \cdot B\omega$  for nonterminal  $B$ , add an  $\epsilon$ -transition from  $A \rightarrow a \cdot B\omega$  to  $B$ .

# *Why This Matters*

- Our initial goal was to find handles.
- When running this automaton, if we ever end up in a state with a rule of the form

$$A \rightarrow \omega \cdot$$

- Then we might be looking at a handle.
- This automaton can be used to discover possible handle locations!

# *Adding Determinism*

- Typically, this handle-finding automaton is implemented deterministically.
- We could construct a deterministic parsing automaton by constructing the nondeterministic automaton and applying the subset construction, but there is a more direct approach.

# *A Deterministic Automaton*

# Constructing the Automaton

- Begin in a state containing  $S \rightarrow \cdot A$ , where  $S$  is the augmented start symbol.
- Compute the **closure** of the state:
  - If  $A \rightarrow a \cdot B \omega$  is in the state, add  $B \rightarrow \cdot \gamma$  to the state for each production  $B \rightarrow \gamma$ .
  - Yet another fixed-point iteration!
- Repeat until no new states are added:
  - If a state contains a production  $A \rightarrow a \cdot x \omega$  for symbol  $x$ , add a transition on  $x$  from that state to the state containing the closure of  $A \rightarrow a x \cdot \omega$
- This is equivalent to a subset construction on the NFA.

# *Handle-Finding Automata*

- Handling-finding automata can be very large.
- NFA has states proportional to the size of the grammar, so DFA can have size exponential in the size of the grammar.
  - There are grammars that can exhibit this worst-case.
- Automata are almost always generated by tools like **bison**.

# *Finding Handles*

- Where do we look for handles?
  - **At the top of the stack.**
- How do we search for handles?
  - **Build a handle-finding automaton.**
- How do we recognize handles?
  - Once we've found a possible handle, how do we confirm that it's correct?

# Question Three:

How do we recognize handles?

# *Handle Recognition*

- Our automaton will tell us all places where a handle might be.
- However, if the automaton says that there might be a handle at a given point, we need a way to confirm this.
- We'll thus use **predictive bottom-up parsing**:
  - Have a deterministic procedure for guessing where handles are.
- There are many predictive algorithms, each of which recognize different grammars.

# *Our First Algorithm: LR(0)*

- Bottom-up predictive parsing with:
  - **L**: Left-to-right scan of the input.
  - **R**: Rightmost derivation.
  - (**0**): Zero tokens of lookahead.
- Use the handle-finding automaton, without any lookahead, to predict where handles are.

## *An Optimization*

- Rather than restart the automaton on each reduction, remember what state we were in for each symbol.
- When applying a reduction, restart the automaton from the last known good state.

# *Representing the Automaton*

- LR(0) parsers are usually represented via two tables: an **action** table and a **goto** table.
- The **action** table maps each state to an action:
  - **shift**, which shifts the next terminal, and
  - **reduce**  $A \rightarrow \omega$ , which performs reduction  $A \rightarrow \omega$ .
  - Any state of the form  $A \rightarrow \omega \cdot$  does that reduction; everything else shifts.
- The **goto** table maps state/symbol pairs to a next state.
  - This is just the transition table for the automaton.

# Building LR(0) Tables

**S** → **E**  
**E** → **T**;  
**E** → **T + E**  
**T** → **int**  
**T** → **(E)**

# *LR(0) Tables*

	int	+	;	(	)	E	T	Action
0	9			8		1	3	Shift
1								Accept
2								Reduce <b>E</b> → <b>T + E</b>
3		5	4					Shift
4								Reduce <b>E</b> → <b>T;</b>
5	9			8		2	3	Shift
6								Reduce <b>T</b> → <b>(E)</b>
7					6			Shift
8	9			8		7	3	Shift
9								Reduce <b>T</b> → <b>int</b>

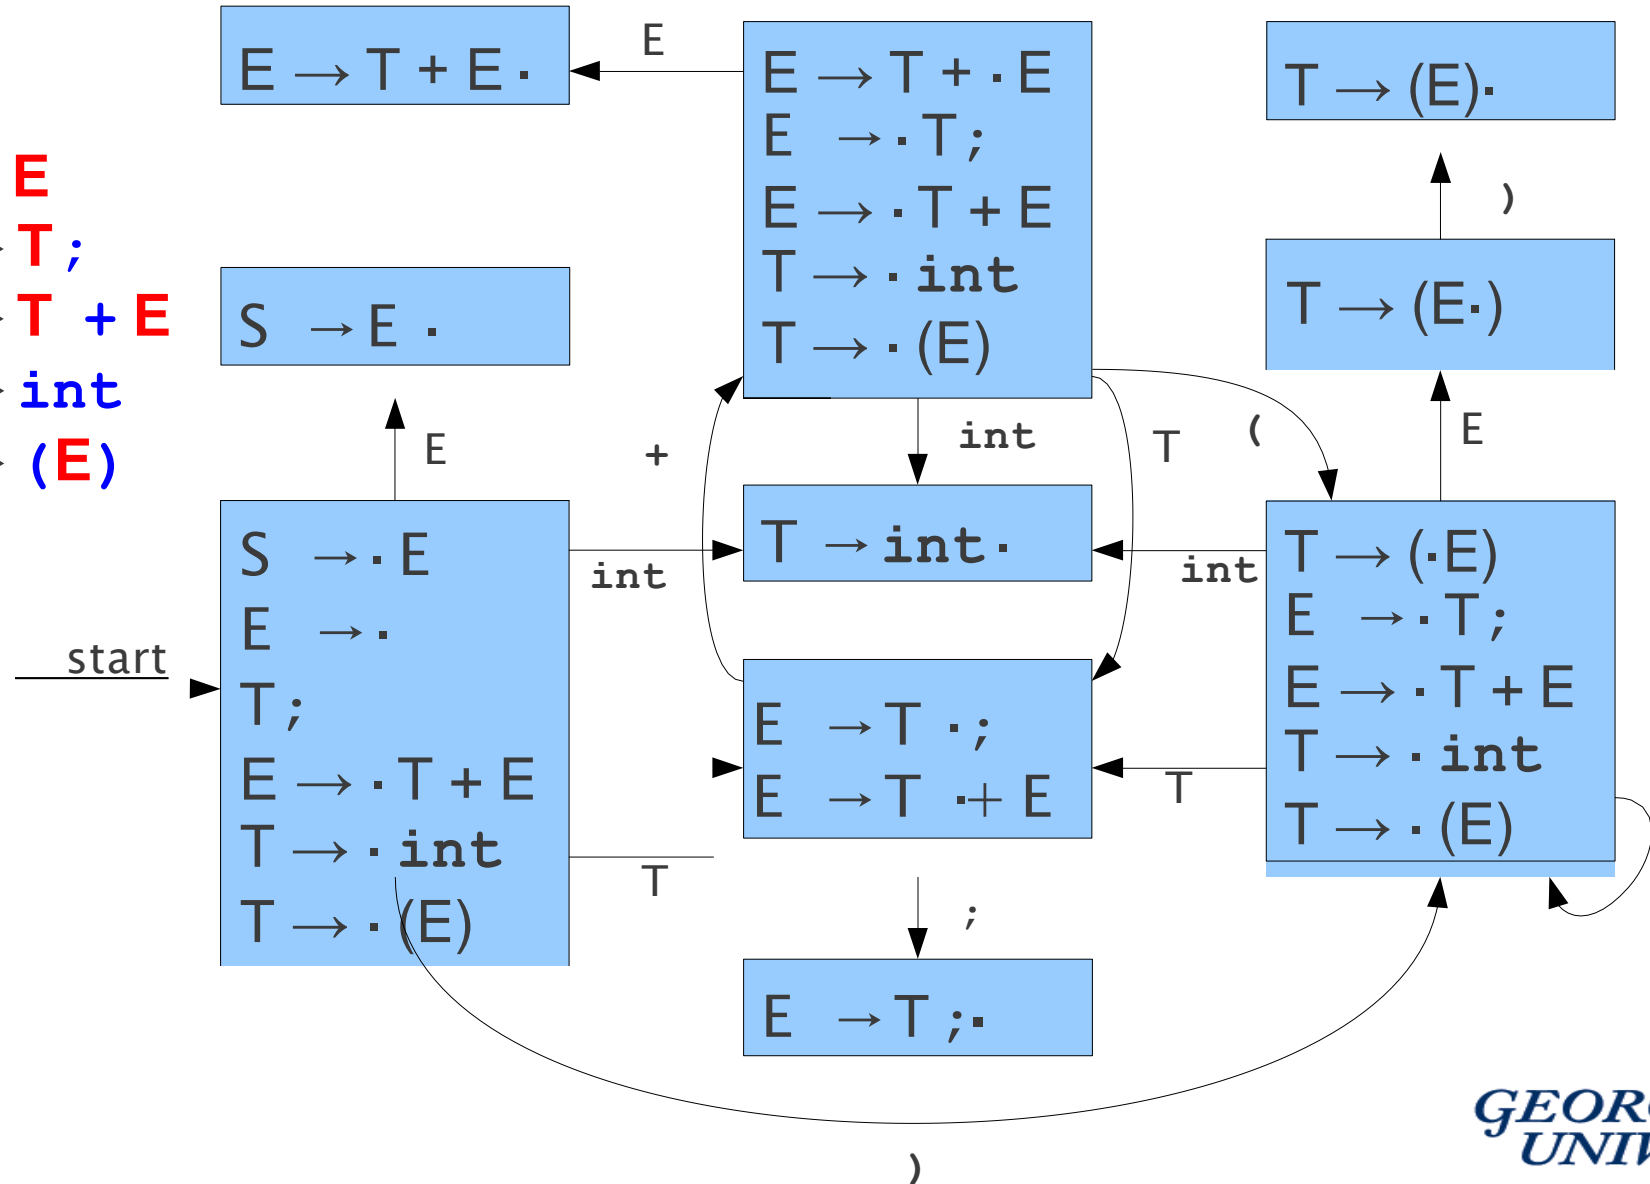

# *The LR(o) Algorithm*

- Maintain a stack of (symbol, state) pairs, which is initially ( $\epsilon$ , 1) for some dummy symbol  $\epsilon$ .
- While the stack is not empty:
  - Let **state** be the top state.
  - If **action[state]** is **shift**:
    - Let  $t$  be the next symbol in the input.
    - Push ( $t$ , **goto[state,  $t$ ]**) atop the stack.
  - If **action[state]** is **reduce**  $A \rightarrow \omega$ :
    - Remove  $|\omega|$  symbols from the top of the stack.
    - Let **top-state** be the state on top of the stack.
    - Push ( $A$ , **goto[top-state,  $A$ ]**) atop the stack.
  - Otherwise, report an error.

# A Non-LR(o) Grammar

# *LR Conflicts*

- A **shift/reduce conflict** is an error where a shift/reduce parser cannot tell whether to shift a token or perform a reduction.
  - Often happens when two productions overlap.
- A **reduce/reduce conflict** is an error where a shift/reduce parser cannot tell which of many reductions to perform.
  - Often the result of ambiguous grammars.
- A grammar whose handle-finding automaton contains a shift/reduce conflict or a reduce/reduce conflict is not LR(0).
- Can you have a shift/shift conflict?

*What error is this?*

# *What error is this?*

*What about this?*

# *What about this?*

# *What do these conflicts mean?*

- Recall: our automaton was constructed by looking for viable prefixes.
- Each accepting state represents a point where the handle might occur.
- A **shift/reduce** conflict is a state where the handle might occur, but we might actually need to keep searching.
- A **reduce/reduce** conflict is a state where we know we have found the handle, but can't tell which reduction to apply.

## *Why LR(0) is Weak*

- LR(0) only accepts languages where the handle can be found with no **right context**.
- Our shift/reduce parser only looks to the left of the handle, not to the right.
- How do we exploit the tokens after a possible handle to determine what to do?

# *A Powerful Parser: LR(1)*

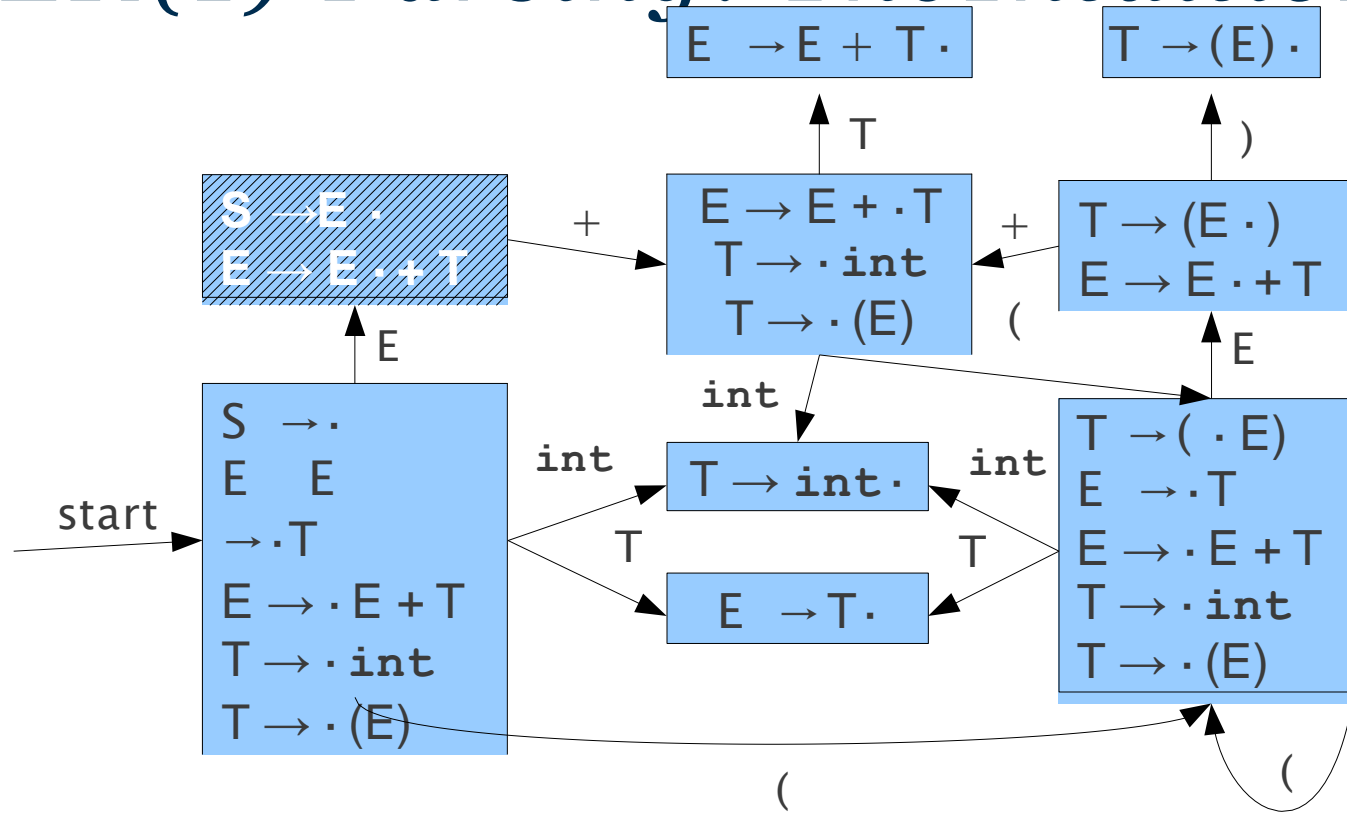

- Bottom-up predictive parsing with
  - **L**: Left-to-right scan
  - **R**: Rightmost derivation
  - (**1**): One token lookahead
- *Substantially* more powerful than the other methods we've covered so far (more on that later).
- Tries to more intelligently find handles by using a lookahead token at each step.

# *LR(1) Parsing: The Intuition*

**S** → **E**  
**E** → **T**  
**E** → **E + T**  
**T** → *int*

## *The Intuition behind LR(1)*

- Guess which series of productions we are reversing.
- Use this information to maintain information about what lookahead to expect.
- When deciding whether to shift or reduce, use lookahead to disambiguate.

# *Tracking Lookaheads*

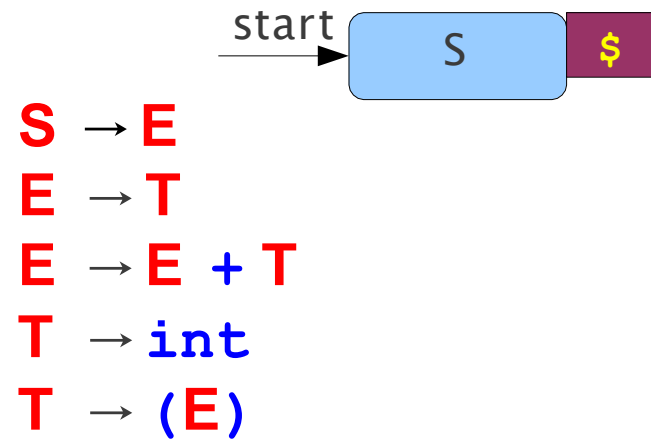

- How do we know what lookahead to expect at each state?
- Observation:
  - There are only finitely many productions we can be in at any point.
  - There are only finitely many positions we can be in each production.
  - **There are only finitely many lookahead sets** at each point.
- Construct an automaton to track lookaheads!

- Begin with a state  $S [\$]$ .
- For each state  $A [t]$ , for each production  $A \rightarrow \gamma$ :
  - Construct states  $A \rightarrow a \cdot \omega [t]$  for all possible ways of splitting  $\gamma = a\omega$ .
  - Add an  $\epsilon$ -transition from  $A [t]$  to each of these states.
  - Add transitions on  $x$  between  $A \rightarrow a \cdot x\omega [t]$  and  $A \rightarrow ax \cdot \omega [t]$
- For each state  $A \rightarrow a \cdot B\omega [t]$ , add an  $\epsilon$ -transition from  $A \rightarrow a \cdot B\omega [t]$  to  $B [r]$  for each terminal  $r \in \text{FIRST}^*(\omega t)$ .

# Constructing LR(1) Automata II

- Begin in a state containing  $\mathbf{S} \rightarrow \cdot \mathbf{E} [\$]$ , where  $\mathbf{S}$  is the start symbol.
- Compute the **closure** of the state:
  - If  $\mathbf{A} \rightarrow a \cdot \mathbf{B} \omega [\mathbf{t}]$  is in the state, add  $\mathbf{B} \rightarrow \cdot \gamma [\mathbf{t}]$  to the state for each production  $\mathbf{B} \rightarrow \gamma$  and for each terminal  $\mathbf{t} \in \text{FIRST}^*(\omega \mathbf{t})$
- Repeat until no new states are added:
  - If a state contains a production  $\mathbf{A} \rightarrow a \cdot \mathbf{x} \omega [\mathbf{t}]$ , add a transition on  $\mathbf{x}$  from that state to the state containing the closure of  $\mathbf{A} \rightarrow a \mathbf{x} \cdot \omega [\mathbf{t}]$ .

# *Structure of LR(1) Automata*

- Every LR(1) automaton simulates two processes simultaneously:
  - An **LR(0) automaton** for finding handles.
  - A **lookahead tracker** for determining what the lookahead is.
- Removing the lookaheads from an LR(1) automaton results in a (much larger) LR(0) automaton for the same grammar.
